

(a) Three years with no campaigns and no data outside the dry season

Number of satellite-field match-ups by year and month. There is no data for 2020, 2021 or 2023, so the 2022-2024 hold-out only contains 2022 and 2024

(b) Only dry season data exists

Bahía de Puno blooms occur during the wet season, which the dataset does not cover at all

Wet season (Dec-Mar) Transition Dry season (Jul-Oct)

(c) The trophic gradient dominates Secchi

Only 73 distinct values in 812 match-ups: readings are rounded to half a metre, so the RMSE of 1.86 m borders the granularity of the reference measurement itself
