

(a) Predicted vs measured

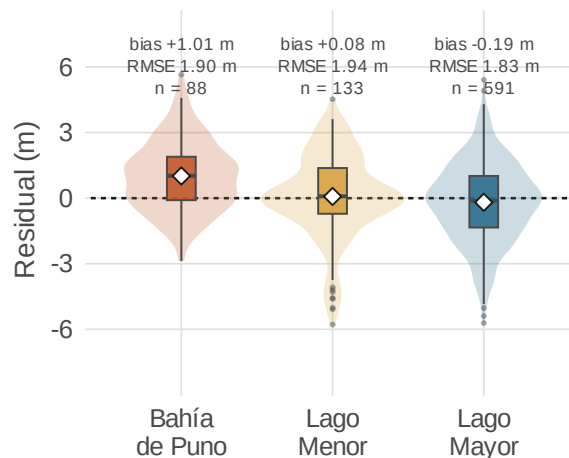

Random Forest, campaign-blocked validation. Dashed line is 1:1

● Bahía de Puno ● Lago Menor ● Lago Mayor

(b) Bias concentrates in the bay

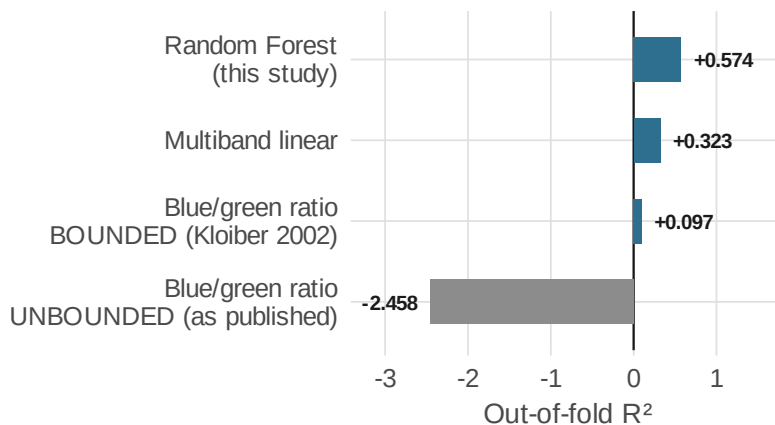

Residuals (predicted - measured) by zone. Diamond is the mean. Bahía de Puno, the most eutrophic zone, +1.0 m

(c) The baseline was misimplemented

Same validation design for all.

The published baseline undid the log without bounds; a single 143 m prediction ruined its R^2

(d) One impossible value ruins R^2

Classical ratio on log scale.

The 143 m point is the one that produced the $R^2 = -2.46$
